Abstract: The study was conducted between 2009 and 2011 in Kanawa Forest Reserve (KFR) in order to determine the impact of anthropogenic pressures and environmental changes of the herbaceous species. The project area was divided into six sites following the variety of land forms in the forest and three transects measuring 100m were laid within each site. Point Centered Quarter (PCQ) sampling method was used. Data obtained were analyzed for relative density, relative frequency, and importance value index. A total of (35) species were identified in KFR out of which 16 species belonged to grasses within three families and 19 genera. The family Poaceae had the highest number, 10 species, the Cyperaceae had 5 species, while the Typhaceae had only 1. 19 species belonged to forbs within fourteen families and 16 genera. The families Asteraceae and Leguminosae: Fabaceae had 3 species each: Rubiaceae had 2 species each. Acanthaceae, Capparidaceae, Euphorbiaceae, Nyctaginaceae, Zygophyllaceae, Portulacaceae, Polygonaceae, Solanaceae, Onagraceae, Labiatae and Commelinaceae all had 1 species each. Simpson's index of diversity was 0.998 and Shannon-Wiener Index was 4.57. This condition indicates complex vegetation. Chi square and its related statistics showed significant positive associations between site I and IV, II and IV, V and VI. Only site I and IV, II and IV, V and VI were significantly negatively associated at ($P < 0.05$). The species with the lowest importance value indices were:- *Pennisetum pedicellatum*, *Polygonum senegalense*, *Vetiveria nigrinata*, *Zornia glochidiata*. These plants therefore require more efforts on conservation.

Keywords: Herbaceous, Biodiversity, Kanawa Forest Reserve (KFR) and Inventory

1. Introduction

According to Hornby (2001), herbs are usually small tender plants, lacking of woody stems above ground. They occur in a wide variety of forms and leaf structures, including annuals, biennials and perennials, and broad-leaved plants (forbs) as well as the grasses. Herbaceous species also constitutes an important vegetative component of the environment due to its diverse ecological importance, including the maintaining of the structure and function of forests (Iwara et al, 2014). In particular they have the role of being an habitat for wild array of animals, the base for complex food web, stabilizing the soil, preventing soil erosion. Furthermore they have an economic relevance such as sources of fodder, food, fuel and medicines, aesthetic and cultural values for vast number of people throughout the

world (Abdullahi, 2011). Some herbaceous species in KFR such as *Euphorbia hirta*, *Zornia glochidiata*, *Mucuna prureins*, *Kyllinga tenuifolia*, *Cyperus sphacelatus*, *Acanthospermum hispidum*, *Physallis angulata*, *Portulaca oleraceae*, *Ludwigia hyssopifolia* are used for medicinal purposes. Both human and animal ailments are treated through the use of these local vegetables. In most instances, these plant species are considered specific for a particular illness but they have occasionally mixed usages. Other species such as *Zornia glochidiata*, *Chloris pilosa*, *Digitaria horizontallis*, *Mucuna prureins*, *Pennisetum pennicelatum*, *Commelina erecta*, *Eragrostis ciliaris* are used for forage/fodder. *Vetivera nigrinata* and *Andropogan gayanus* are also raw material for the production fuel. *Typha domingensis* is an invasive herb that has a strong and possibly expanding presence in the wetter habitats of the reserve. Herbaceous

species however plays a major role in improving water penetration into soils and adding organic matter that improves moisture holding capacity and plant growth. It indeed plays important functions relating to productivity and environmental health by reducing the velocity of runoff (Department of Environment and resource management, 2010). Notwithstanding its small stature, herbaceous species has huge ecological significance of mediating carbon dynamics and energy flow and influencing the cycling rates of essential nutrients, including N, P, K and Mg (Gilliam, 2007). The herb community of tropical forests is very little known, with few studies addressing its structure quantitatively. Even with this scarce body of information, it is clear that the herbs are a rich group, comprising 14 to 40% of the species found in total species counts in tropical forests. This stratum remains an underappreciated aspect of forest ecosystems (Gilliam, 2007). The quantitative plant diversity inventories are the fundamental tool for conservation and management of tropical forests (Campbell 1994), but as far as KFR are concerned they are limited and quantitative inventories of understory species are still lacking. The

documentation and classification of this unique and often neglected vegetation community may enable efforts to be made for biological conservation (Jennings *et al.*, 2009; Ahmad and Ehsan, 2012). The problem is that due to over collection and climate change several species are fast disappearing. The herbaceous flora of KFR is one of the diverse among the savanna vegetation types of Northern Nigeria and this could mainly be due to climatic, edaphic and human impact. Although studies have been undertaken in other forest reserves in Nigeria, Kanawa Forest Reserve (KFR) (since establishment between 1940 and 1945 has not received such scientific attention. It therefore became imperative to take stock of the status of the herbaceous vegetation of Kanawa forest with a view to deriving appropriate conservation measures. The aim of the study was to obtain an inventory of the herb species of (KFR), in order to determine their relative importance and diversity.

2. Materials and Methods

2.1. The Study Area

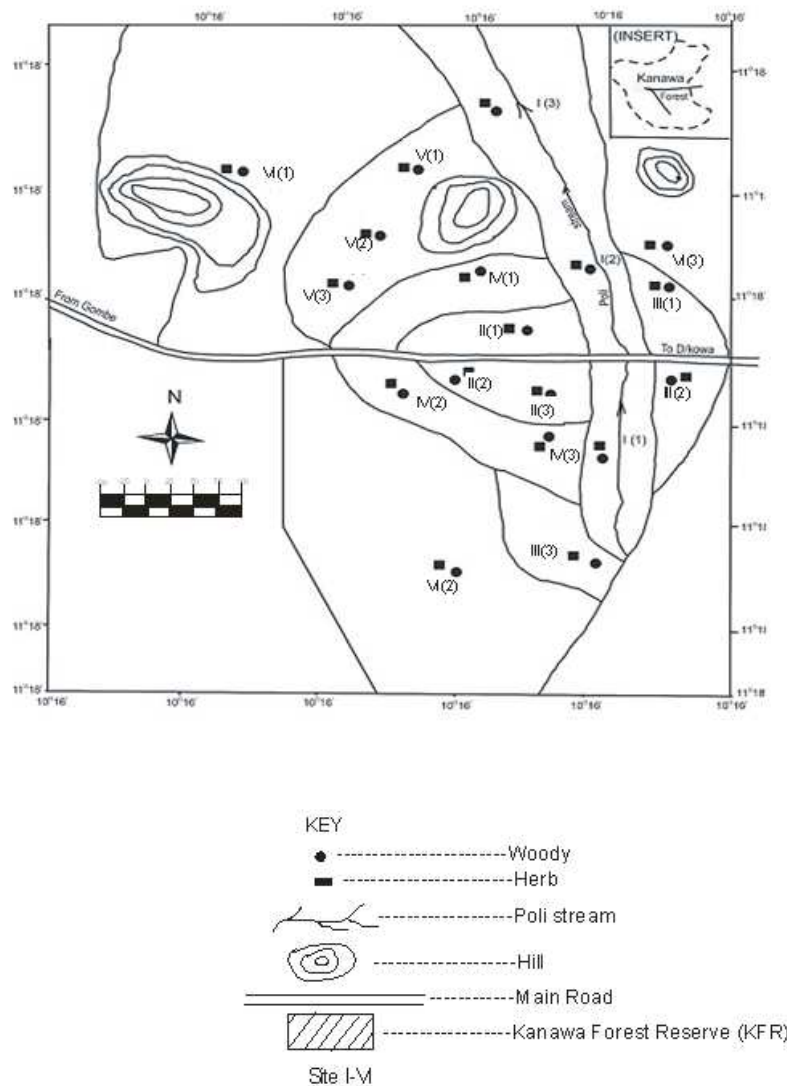

Figure 1. Map showing the study sites and location of sampling points in Kanawa Forest Reserve.

KFR is located in the North Eastern part of Nigeria in Yamaltu/Deba Local Government Area of Gombe State and it lies in the Southern part of the Sudan Savanna between latitude 10°16'N and 10°18'30"N longitude 11°18'10"E and 11°22'09"E and at an altitude of 336-390 mamsl. The size of the forest was 41 hectares (Gombe Native Authority, 1945) and it was gazetted as a forest reserve in 1953. At present the Kanawa Forest Reserve is presently 53 hectares due to the acquisition of surrounding farmlands by Gombe State Government.

The terrain is generally undulating, with dendritic shallow V-shaped drainage (Samaila, 2011). The soil types were loamy sand, sandy and sandy loam types (Abba *et al.*, 2013)

The climate is characterized by two distinct seasons: The rainy season one that lasts from April through October and the dry ones that goes from November to March. The rainfall pattern is bimodal with an annual total which ranges from 658- 923mm. The mean annual temperature ranges from 32.2 to 32.80C. Six sites were used for vegetation sampling following the selecting criteria of topography, soil, and vegetation types. The vegetation of (KFR) is a mosaic made up of dense Sudan savanna vegetation especially around the hilly part of the reserve (Site VI). Marshy(Site IV), riparian (Site I), lowland rainforest vegetation near the Poli stream (Site II) grassland with tall grasses (Site III) and thorn vegetation in the drier part of the forest (Site V). In each site, three sampling locations were identified (Fig 1).

2.2. Sampling Procedure and Methodology

The point centred quarter (PCQ) method was employed (Cottam and Curtis 1956; Dix, 1971; Abdullahi, 2010). Three transects (1, 2, 3) of 100m long each were laid per site. There were 10 sampling points per transect giving a total of 30 sampling points. On each sampling point four quarters were demarcated and the nearest herb plant in terms of distance from the point to the center of the herb plant. Readings were recorded in meters within each quarter. This was done for all the sampling points on each transect.

2.3. Data Collection and Analysis

In each sampling point all nearest living herb species encountered were listed. In each site, all nearest living herb plant were measured with measuring tape in each quarter and recorded. Species encountered were identified on site with the help of field guides and floras and texts (Blair, 1976; Lowe and Stanfeild,1974; Akobundu and Agyakwa, 1998). Also morphological characteristics involving fruits, flowers, leaves and stem, bark and sap were used for identification. The specimens were collected and compared with herbarium specimens of the Biological Sciences Programme, Abubakar Tafawa Balewa University, Bauchi, Nigeria. Nomenclature of the species follows Hutchinson and Dalzeil (1972).

Data obtained were quantitatively analyzed for Relative

density (RD), Relative frequency (RF) following Curtis (1959), and the relative values were summed up to obtain Importance Value index (IVI) (Misra,1968, Dallmier,1992; Sabogal,1992; Abdullahi, 2010). The formulae used to calculate RD, RF and (IVI) are as follows:-

RD = (number of individuals of a species)/ (total number of individuals of all species) x 100.

RF= (frequency of one species)/ (sum of all frequencies) x 100

IVI = sum of (RF+ RD) /2

The value of IVI may range from 0 to 200%. Dividing it by 2 will result in a figure that ranges from 0 to 100%. This value is referred to as the importance percentage.

Species diversity was calculated using Simpson's index (Simpson, 1949) with this formula:

$D = [N(N-1)] / [\text{summation of } n(n-1)]$, where D is the diversity index, N is the total number of individuals of all plant species found, n is the number of individuals of a particular species.

Species diversity index was also calculated using the Shannon-Weiner index (Shannon, 1948)

$$H' = - \sum_{i=1}^R P_i \ln P_i$$

Where H' is the = Shannon –Weiner diversity index

P_i = is the proportion of each species in the sample.

R = represents the total number of species

Chi-Square analysis was calculated using the following formulae:

$\chi^2 = n (ad-bc)^2 / (a+b) (c+d) (a+c) (b+d)$, while the correlation coefficient was obtained as follows: i (Causton, 1988)

$r = ad-bc / \sqrt{\{(a+b) (c+d) (a+c) (b+d)\}}$ -ii

From the above equations;

n = number of species in the data set

a = number of species common to sites A and B

b = number of species present in site A but not B

c = number of species present in site B but not A

d = number of species absent in site A and B

χ^2 = chi-square

r = correlation coefficient

3. Results and Discussion

A total of (35) species of herbs were identified out of which 16 species belonged to grasses within 3 families and 19 genera and 19 species belonged to forbs within 14 families and 16 genera within an area of 53 hectares, of which 10 species were encountered in the riparian (site I), 8 in lowland rainforest vegetation near Poli stream (Site II), 9 in grassland with tall grasses (Site III), 8 in Marshy (Site IV), 7 in thorn vegetation in the drier part of the forest (Site V), and 13 in the dense Sudan savanna vegetation especially around the hilly part of the reserve (Site VI) respectively. A total of 14 families were recorded for forbs

(Table 1). In the study area, the families Asteraceae and Leguminosae: Fabaceae had 3 species each; Rubiaceae had 2 species each. Acanthaceae, Capparidaceae, Euphorbiaceae, Nyctaginaceae, Zygophyllaceae, Portulacaceae, Polygonaceae, Solanaceae, Onagraceae, Labiatae and Commelinaceae all had 1 species each. A total of three families were recorded for grasses (Table 2). The family Poaceae had the highest number, 10 species. The family Cyperaceae had 5 species; Typhaceae had only 1 species.

From the above results, the families that had the most common herb species were Poaceae and Cyperaceae. The Poaceae family is one of the most widely distributed and abundant groups and important family of the earth's flora. Their success results from their tolerance of grazing herbivores and fire, their varied means of reproduction, and their versatility in photosynthesis. These families were also known to be native species in most savannah-woodland mosaics in Africa and more typical of the Sudano-Sahelian zone. A similar study was carried out by Atiku and Bello (2011) at Wassaniya Forest Reserve of Sokoto State (Nigeria), using the point centered quarter method. Another investigation was carried out in Yankari Game Reserve (YGR), in the Savanna-Woodlands of Northern Nigeria by Abdullahi (2010). The number obtained in the present study was higher than that of Wassaniya Forest Reserve probably because of the size, location, soil composition, soil types and climatic factors which gave rise to a higher number of species. It was however lower than that of Yankari Game Reserve, because of the statute of Yankari as a game reserve and the moist-warm climate, geological and topographic nature of the area.

Table 3, reveals the relative density of herbs. The highest value in the reserve was *Typha domingensis* (37.50%) revealing that it was the most abundant species in the forest because *Typha* species were often among the first wetland plants to colonize areas of newly exposed wet mud, with their abundant wind dispersed seeds which provides a greater reproductive capacity. Buried seeds could survive in the soil for long periods of time and they germinate best with sunlight and fluctuating temperatures. The plants also spread by rhizomes, forming large, interconnected stands with extensive root systems which provides a rapid growth and makes them invasive and proliferative.

The lowest value was recorded on *Polygonum senegalense* (2.50%), probably due because of the continuous use for removal of ecto parasites from livestock and also orally administered to cattle for managing unstated diseases. The herb species *Hyptis suaveolens* had the highest relative densities (15.00%) at site I and II probably because *Hyptis* shows strategy for better survival and establishment. It exhibit vigorous growth in the forest. Fenner (1985) reported that a number of vegetative characters are helpful in the heavy proliferation of *Hyptis* such as small seed size, prolific seed production forming persistent propagule bank within short period, seed dimorphism, autogamic and allogamic mode of reproduction, good proliferation from the perrenating

rootstock, probable allelochemicals and presence of essential oil conferring resistance to it against variety of pathogens. Factors favoring the growth of *Hyptis* is the small seed size, which easily penetrates into cracks or small openings in the soil. Reduction in size along with large number of seeds has also been associated with predator avoidance as reported by Fenner (1985). Seed dimorphism in *Hyptis* is helpful in its germination across a range of temperature conferring year round seed germination.

Typha domingensis had the highest relative densities (15.00%) at site I and *Kyllinga tenuifolia* at site IV. Those species were high because of their extensive root system and they often exclude other plants with their dense canopy. The species *Vetiveria nigritana* had the lowest relative density (4.17%) at site VI, because the roots have been used continuously for their fragrance and are woven into fragrant-smelling mats and fans by the locals living around the reserve. Lastly, *Vetiveria nigritana* is beneficial to poor farmers because it provides traditional cost effective ways to fight infections and diseases. The plant also contains active ingredients used in traditional medicine and as botanical pesticide.

Euphorbia hirta (8.16 m²/ ha) had the highest absolute density in the reserve, hence the most densely populated species. This was because it grows on all type of soils and it reproduces by seeds up to 3,000 seeds per plant. The plant is dispersed in an active way by projection or in a passive way by the activity of ants. Herbivours also play a key role in long distance dispersal of propagules (Milton and Dean, 2001) enhancing local colonization processes and plant diversity (Oloff and Ritchie, 1998). The lowest value was recorded on *Zornia glochidiata* (0.600 m²/ ha), because the species is considered a good fodder plant for animals and leaves are sources of food and medicine. *Chloris pilosa* and *Chamaecrista mimosoides* had the highest absolute density (5.64 m²/ ha) in site V. The two species belongs to Poaceae and Leguminosae: Fabaceae family which is known to be propagated by seeds. The lowest absolute density (0.56 m²/ ha) was recorded on *Digitaria horizontalis* at site I, because it was highly grazed upon as sources of fodder by animals. This study was consistent with the findings of (Abdullahi *et al.*, 2009; Atiku and Bello, 2011) at YGR, Bauchi and Wassaniya Forest Reserve, Sokoto State, Nigeria.

The species with the highest absolute density in the reserve was *Mucuna pruriens* (46.36 m²/ ha), hence the most densely populated. This shows that this herb had the highest number of species per unit area in the reserve. This high number could be because it was rapidly dispersed by seeds and the associated processes of germination, seedling establishment and survival were rapid. This finding was consistent with that of (Harper's, 1977).

Achyranthes aspera (8.54 m²/ ha) was the species with the least number in the forest. It is highly sought for by humans as sources of food and medicine. *Abrus precatorius*, *Ipomoea asarifolia*, *Luffa cylindrica* and *Mucuna pruriens* had the highest absolute density in site I while the lowest values (3.13%) was recorded on *Combretum racemosum*

and *Abrus precatorius*. *Mucuna pruriens* (22.50) had the highest relative densities at site III while the lowest value was recorded on *Achyranthes aspera* (7.50).

Relative density was high because site III contains loamy sand, minimum amounts of moisture content, high organic matter content, total nitrogen and available phosphorus, with high amounts of exchangeable bases.

The relative frequency of herbs for KFR is presented in Table 4. *Kyllinga tenuifolia* and *Cyperus spachelatus* had the highest grass frequency (80%) in the reserve hence the most frequent grass species. The high frequency could probably be because of the presence of seeds that could easily be dispersed together with their rapid regeneration abilities. The lowest frequency in the reserve was recorded on *Acanthospermum hispidum*, *Fimbristylis ferruginea*, *Fimbristylis meliacea*, *Pennisetum pedicellatum*, *Physalis angulata*, *Polygonum senegalense*, *Vetivera nigrinata*, *Zornia glochidiata*. This could be because they were highly grazed upon by animals. The herb species *Commelina erecta* and *Hyptis suaveolens* had the highest frequencies at site II and *Kyllinga tenuifolia* had the highest frequency at site IV. The species *Digitaria horizontalis*, *Ludwigia hyssopifolia*, *Physalis angulata*, *Tridax procumbens*, *Chloris pilosa* had the lowest frequencies at site I. *Chloris pilosa*, *Vernonia cineria*, *Portulaca oleracea*, *Euphorbia hirta* had the lowest frequencies at site II. *Digitaria horizontalis*, *Kyllinga tenuifolia*, *Fimbristylis ferruginea*, *Fimbristylis meliacea*, *Vetivera nigrinata*, *Eragrostis ciliaris*, *Eragrostis tremula*, and *Spermacose viticilata* had lowest frequencies at site III. *Tribulus terrestris* had lowest frequencies at site IV. *Euphorbia hirta*, *Tridax procumbens*, *Commelina erecta*, *Polygonum senegalense*, *Boerhavia diffusa*, *Cenchrus biflorus*, *Pennisetum pedicellata*, *Alysicarpus vaginalis* had lowest frequencies at site V. *Commelina erecta*, *Eragrostis tremula*, *Acanthospermum hispidum*, *Dactyloctenium aegyptiaca*, *Boerhavia diffusa*, *Cenchrus biflorus*, *Alysicarpus vaginalis*, *Zornia glochidata* had the lowest frequencies at site VI. These low values could be due to human impact and their importance as sources of medicine, forage /fodder and food.

Cyperus spachelatus and *Kyllinga tenuifolia* had the highest relative frequencies (41.91%) in the reserve. This shows that the species had random distributions because the environmental conditions and resources were consistent and their modes of dispersal are sporadic. The lowest relative frequencies (5.26%) were recorded on *Polygonum senegalense*. *Euphorbia hirta*, *Hyptis suaveolens* and *Typha domingensis* had highest relative frequencies at site I. *Cyperus spachelatus* (17.65%) had the highest relative frequency at site III. *Vernonia cineria*, *Portulaca oleracea* and *Euphorbia hirta* had lowest relative frequencies of (4.17%) at site II. All this showed clumped distribution of species mainly because water only reaches the surface of the terrain in specific places and there is just enough to support their growth. This study was also in line with the works of (Abdullahi and Sanusi, 2006) and of Atiku and Bello (2011) who studied herbaceous species in Yankari

game reserve, Bauchi State and Wasaniya Forest Reserve, Sokoto State, Nigeria.

From Table 5, the herb species with the highest Importance Value Index (IVI) in the whole forest reserve was *Typha domingensis* (43.81%). The herb species *Scleria verrucosa* (3.63%) had the lowest IVI in the reserve. The herb species *Typha domingensis* had the highest IVI of (15.83%) at site I while the lowest was recorded for *Scleria verrucosa* (3.63%) at site V. The importance value, or the importance percentage, gives an overall estimate of the influence of importance of a plant species in the community.

The IVI is imperative at comparing the ecological significance of species and it indicates the extent of dominance of a species in the structure of a vegetation stand (Curtish and McIntosh, 1951; Rosenzweig, 1995; Abdullahi, 2010). IVI is also a reasonable measure to assess the overall significance of a species since it takes into account several properties of the species in the vegetation. The IVI was calculated as per Curtis and McIntosh (1951). The importance value indices IVI of the herbaceous species were generally low in the study area. The low IVI values could be due to different species with few individuals represented in each herbaceous species. This is consistent with the works of (Abdullahi, 2010). All these species were characteristic of Sudan Savanna vegetation types. The grasses were shorter than in the Guinea Savanna zones, and they had different characters. Most of the grasses were annuals because of drought-stress in the long dry period. A number of perennials grow vigorously too (Broekhuysen and Allen, 1984; Vierich and Stoop, 1990).

The results of Simpson's index of diversity (1-D) was (0.998), while Shannon-Weiner index of Diversity for the study area was (4.57) for the herb species. The values were high indicating a more complex and healthy community with greater variety of species allowing for more species interactions. This will ensure greater system stability, and indicating good environmental conditions. The high diversity could also be due to the high fertility related parameters and high moisture contents in some sites. It could also be due to the position of Kanawa Forest as a forest reserve.

A similar study was carried out by Abdullahi (2010) where he reported Simpson's index of diversity for herbs in Yankari National Park as (0.998). Richard *et al.*, (2011) also reported Simpson's index of diversity as (0.957) for the Miombo woodland of Bereku Forest Reserve, in Tanzania. These values were higher than those of the present study due to size and higher enforcement of protection laws.

The Shannon-Wiener Index of diversity (H') was reported by Richard *et al.*, (2011) to be 4.27 for the Miombo Woodlands of Bereku Forest Reserve and 2.76 in Khadimnagar National Park of Bangladesh as reported by Sobuj and Rahman (2011). The value of 4.27 is lower than the 4.57 obtained in the present study. The higher value observed in this study may be due to riparian vegetation found along the Poli stream that transverse part of the KFR along with its concomitant high fertility and variation in the

ecotypes within the KFR.

The results of the association, similarity and correlation between site (Table 6) revealed that site III and VI had the highest association values (10.7905), while the lowest value (0.064815) was recorded in site I and II. Three positive associations at site I and IV, II and IV, V and VI. Only site I and IV, II and IV, V and VI were significantly negatively associated at ($P < 0.05$). Sites I and III (23.58), had higher

sum of chi-square (S_x). The S_x (sum of chi-square) and S_r (sum of correlation coefficient) values were similarly less than the total number of species in the data set (35) and $>$ greater than 1(one) except for three positive relationships depicting weak relationships and heterogeneity of the flora of KFR. According to Kumar *et al.*, (2006) species distribution in areas with high diversity is always heterogeneous.

Table 1. Families and species of forbs identified at Kanawa Forest Reserve (KFR), Gombe State, Nigeria during 2010-2011.

4. Conclusion

Kanawa Forest Reserve is dominated by the following herb species: *Cyperus sphacelatus-Hyptis suaveolens-Typha domingensis* complex. The presence of *Typha* being an invasive herb species could also be a threat to the native species within the reserve. In order to protect the forest reserve from further encroachment from human activities such as harvesting the herbs for medicinal purposes, and animals foraging on the grasses, the reserve need to be fenced and additional guards be obtained. It was also concluded that the species with the lowest importance value indices were:- *Pennisetum pedicellatum*, *Polygonum senegalense*, *Vetiveria nigrinata*, *Zornia glochidiata*. These plants therefore require more efforts on conservation.
